## Eessõna

Käesolev väljaanne esitab Eesti Meditsiinilise Sünniregistri (EMSR) ja Eesti Abordiregistri (EAR), alates 02.06.1999 nimega raseduskatkestusandmekogu, andmeid. Tabelites puuduvad EMSRi 1993.–1996. aasta andmed on esitatud registri varasemates väljaannetes.

EMSR töötab alates 1992. aastast. Registri pidamise eesmärk on sündimuse mõõtmine Eesti Vabariigis. Andmete esitajad EMSRile on kõik Eestis sünnitusabi osutavad haiglad. Andmete kogumise alusdokument on sünnikaart (lisad 1, 2 ja 3). Sünnikaart täidetakse iga Eesti territooriumil toimunud sünni (elusalt või surnult sündinu) kohta.

EAR asutati 1994. aastal ja tema pidamise eesmärk on pidev ning süstemaatiline informatsiooni kogumine Eesti tervishoiuasutustes aset leidnud abortide kohta. Alates 1996. aastast põhineb riigi abordistatistika EARi andmetel. Registrile andmete esitajad on kõik Eesti territooriumil rasedusi katkestavad ja katkenud rasedusega naistele arstiabi osutavad tervishoiuasutused (k.a eraarstid). Andmete kogumise alusdokument on abordikaart (lisad 4, 5 ja 6), mis täidetakse iga tervishoiuasutuses aset leidnud raseduse katkemise või katkestamise kohta.

Andmete esitajad saadavad täidetud sünni- ja abordikaardid kuude kaupa registrisse. Sünni- ja abordiregistris toimub: andmete kontrollimine ja täpsustamine, kodeerimine, andmete sisestus arvutisse, andmete standardtöötlus ja andmetöötlus vastavalt päringutele, andmete säilitamine ning paberdokumentide arhiveerimine.

1998. aastal EARi andmebaasi kvaliteet halvenes oluliselt, sest alates 06.11.1998 (sotsiaalministri käskkiri nr 267) peatati abordikaartide saatmine registrisse. 02.06.1999 (sotsiaalministri määrus nr 43) lubati abordikaartide saatmist küll jätkata, kuid abordikaardile ei lubata enam märkida naise isikukoodi.

## Preface

The following report is derived from the data of the Estonian Medical Birth Registry (EMSR) and the Estonian Abortion Registry (EAR). Data of EMSR about 1993–1996, which are missing in the tables of the present publication are presented in earlier reports of the registry.

The EMSR has been working since 1992. The objective of the Registry is to measure fertility in the Republic of Estonia. Data are gathered from all hospitals rendering obstetric services in Estonia. The primary document for gathering data is the Birth Card (Annexes 1, 2 and 3). A Birth Card is filled in for every birth (live or stillbirth) in the territory of Estonia.

The EAR started in 1994. The objective of the Registry is the continuous and systematic collection of information about abortions in Estonian health care institutions. Since 1996, national abortion statistics has been based on the data of the EAR. Data are gathered from all of the health care institutions (incl. private doctors) who have done abortions or have provided medical care to women who have had an abortion. The primary document for gathering data is the Abortion Card (Annexes 4, 5 and 6), which is filled in for every abortion that has taken place in a health care institution.

The filled in Birth Cards and Abortion Cards are sent to the registries monthly. At the registries the following actions are carried out: control and correction of data, coding, input of data, standard data processing and data processing according to requests, saving of data and placing of paper documents into an archive.

In 1998 the quality of the database of the EAR decreased, because beginning from 06.11.1998 sending of Abortion Cards to the Registry was stopped (Order No. 267 of the Minister of Social Affairs). Beginning from 02.06.1999 collection of Abortion Cards resumed (Decree No. 43 of the Minister of Social Affairs), however, inclusion of a personal identification number of a woman was not permitted.

## **Tänuavaldused**

Oleme sügavalt tänulikud professor Mati Rahule, Eksperimentaalse ja Kliinilise Meditsiini Instituudi epidemioloogia ja biostatistika osakonna juhatajale, nõuannete eest käesoleva kogumiku koostamisel.

Täname koostöö eest kõiki EMSRi ja EARi andmeesitajaid, samuti Statistikaameti rahvastikustatistika sektori töötajaid.

## **Acknowledgments**

We are deeply thankful to Professor Mati Rahu, Head of the Department of Epidemiology and Biostatistics of the Estonian Institute of Experimental and Clinical Medicine, for advice in composing this book.

We are grateful also to all the data reporters of EMSR and EAR, and the employees of the Population Statistics Section of the Statistical Office of Estonia for their cooperation.

# KOKKUVÕTE

## Sünnid, sündimus

Aastatel 1992–1998 sündimus Eestis vähenes. Kui 1992 oli sündide üldarv 18 191 ja elussündide arv 1000 fertiilses eas naise kohta 48,6, siis 1998 olid need näitajad vastavalt 12 204 ja 35,1. 1999 ja 2000 sündimus veidi suurenes, kuid 2001 uuesti vähenes. Aastal 2001 oli sündide üldarv 12 690 ja elussündide arv 1000 fertiilses eas naise kohta 36,8. Maakondade järgi oli elussündide arv 1000 fertiilses eas naise kohta kõige kõrgem Valgemaal, järgnesid Lääne-Viru- ja Jõgevamaa; kõige madalam oli see näitaja Ida-Virumaal, küllaltki madal ka Harjumaal.

## Perinataalne suremus

1992–2001 on perinataalne suremus Eestis vähenenud: 1992. aastal oli perinataalsuremuskordaja 1000 sünni kohta 20,1, 2001. aastal 8,0. Perinataalse suremuse vähenemine nimetatud ajavahemikul on tingitud varase neonataalse suremuse ja surnultsündimuse vähenemisest (varane neonataalne suremus on vähenenud enam kui surnultsündimus).

Perinataalne suremus on vähenenud nii kõrgema ehk III etapi haiglates (1000 või enam sünni aastas) kui väiksema sündide arvuga II etapi haiglates (alla 1000 sünni aastas), jäädes III etapi haiglates siiski veidi suuremaks. See on mõistetav, sest kõrgema ehk III etapi haiglatesse (Ida-Tallinna Keskhaigla, Lääne-Tallinna Keskhaigla ja Tartu Ülikooli Kliinikum) suunatakse kõrge riskiga sünnitajad ka madalama etapi haiglate teeninduspiirkondadest.

## Sünnitajad

Ajavahemikul 1992–2001 on sünnitajate keskmine vanus suurenenud (25,5 aastalt 27,1 aastani). Keskmine vanus on suurenenud nii esmas- kui korduvsünnitajatel. Koos sünnitajate vanuse suurenemisega on suurenenud ka vastsündinute isade keskmine vanus. Sünnitajate hulgas on vähenenud töötavate naiste ning suurenenud töötute, koduperenaiste ja üliõpilaste osakaal. Oluliselt on muutunud sünnitajate perekonnaseis. Vähenenud on registreeritud abielus olevate sünnitajate (1992. aastal 66,3%, 2001. aastal 43,4%) ning suurenenud vabaabielus olevate ja vallaliste sünnitajate osakaal. Eestlaste osatähtsus sünnitajate hulgas tõusis aastatel 1992–1993 (70,4%lt 73,6%ni), kuid edaspidi see vähehaaval langes ja oli 2001. aastal 70,1%.

1992–2001 on suurenenud nende sünnitajate osatähtsus, kes võtavad ennast rasedusega arvele juba enne 12. rasedusnädalat. Kui 1992. aastal moodustasid need naised kõikidest arvel olnutest 49,7%, siis 2001. aastal 67,6%. Samal ajal on suurenenud antenataalsete külastuste arv. 2001. aastal külastas iga sünnitaja raseduse ajal arsti või ämmaemandat keskmiselt 10,3, sealhulgas naistearsti 9,7 korda.

Raseduse ajal tehtud uuringutest on oluliselt suurenenud ultraheliuuringute arv enne 21. rasedus- nädalat. 1992. aastal tehti iga 100 sünnitaja kohta ultraheliuuring 30le, 2001. aastal 86le sünnitajale. Rasedusaegsete riskitegurite ja tüsistuste hulgas on suurenenud varasema keisrilõike, aneemia, ähvardava raseduse katkemise ning vähenenud hüpertooniatõve, preeklampsia, neeruhaiguste ja ähvardava enneaegse sünnituse osatähtsus.

1992–2001 on märgatavad muutused toimunud sünnitamisviisis, vähenenud on vaginaalsete sünnituste ja suurenenud keisrilõigete osatähtsus. Kui 1992. aastal tehti keisrilõige 6,4%le, siis 2001. aastal 15,6%le sünnitajatest. Enneaegsete sünnituste osakaal on aastatel 1992–2001 mõnevõrra vähenenud (6,6%lt 5,8%ni).

Sünnitusel läbiviidud toimingutest on 1992–2001 suurenenud loote elektroonse jälgimise, lootevere pH määramise, loote põie avamise ja sünnituse indutseerimise ning vähenenud episio-

ja perineotoomia osatähtsus. Sünnituspuhustest diagnoosidest on suurenenud asfüksia esinemissagedus.

Peresünnituste osatähtsus on pidevalt suurenenud: 1992. aastal moodustasid peresünnitused 12,6% kõikidest sünnitustest, 2001. aastal 56,2%. Peresünnituste protsent on kõige suurem kõrgema etapi haiglates ja kõige väiksem suuremates II etapi haiglates.

### ***Vastsündinud***

Sündide arv ei olnud aastaringelt ühtlane. Kümne aasta jooksul (1992–2001) sündis kõige rohkem lapsi varakevadel (märtsis) ning kõige vähem hilissügisel (novembris). Poisse sündis veidi enam (51,6%) kui tüdrukuid (48,4%).

Aastatel 1992–2001 on veidi suurenenud haiglas ja vähenenud väljaspool haiglat toimunud sündide osakaal. Haiglas toimunud sündide hulgas on olnud vähem surnutsünde kui väljaspool haiglat ja teel haiglasse toimunud sündide hulgas.

Vastsündinute keskmine sünnikaal on 1992–2001 üldiselt suurenenud (54 g võrra). Aastal 2001 oli vastsündinute keskmine sünnikaal 3489 grammi (poistel 3561 g ja tüdrukutel 3413 g). Kõige enam sünde oli kaaluvahemikus 3500–3999 grammi, varases neonataalperioodis surnud lapsi kaaluvahemikus 500–999 grammi.

Vastsündinutel diagnoositud haigustest on vähenenud respiratoorse distressi ja sünnitrauma osatähtsus. Enam on hakatud lapsi esimese elunädala lõpuks koju kirjutama või suunama edasisele ravile teise haiglasse. 1992. aastal olid 7 päeva vanuseks saanud lastest endiselt vastsündinute osakonnas 8,4%, 2001. aastal 1,8%.

### **Abordid**

Ajavahemikul 1992–2001 on Eestis nii abortide üldarv kui abortiivsuskordaja pidevalt vähenenud. 1992. aastal oli legaalselt indutseeritud (s.t naise omal soovil või meditsiinilistel näidustustel tehtud) abortide üldarv 25 803 ja abortide arv 1000 fertiilses eas naise kohta 69,6, 2001. aastal olid need näitajad vastavalt 11 656 ja 34,0. Legaalselt indutseeritud abortide arv 100 elussünni kohta oli 2001. aastal 92,4, mis on samuti madalam kui 1992. aastal – 143,3.

Maakondade järgi oli abortide tase (nii nende arv 1000 fertiilses eas naise kohta kui 100 elussünni kohta) 2001. aastal kõige kõrgem Ida-Virumaal ning kõige madalam saartel (Saare- ja Hiiumaal).

2001. aastal aborti teinud naiste keskmine vanus oli 28,2 aastat; umbes neljandik (25,3%) nendest ei olnud kordagi sünnitanud. Enam kui pooled aborti teinud naistest (57,9%) ei kasutanud vahetult enne rasestumist mingeid rasestumisvastaseid vahendeid. Vanuse järgi oli rasestumisvastaseid vahendeid mittekasutanute osakaal suurem väga noorte (alla 20-aastaste) ja fertiilse ea lõpus olevate naiste hulgas. Eestlaste osatähtsus aborti teinute hulgas oli 57,5%, seega väiksem kui sünnitanute hulgas (70,1%). Aborti teinud naiste hulgas oli enam vallalisi kui sünnitanute hulgas.

Kõikidest 2001. aastal Eesti tervishoiuasutustes asetleidnud abortidest moodustasid enamiku (82,9%) legaalselt indutseeritud abordid, keskmine raseduskestus legaalse aborti korral oli 7,7 nädalat. Abordi meetoditest kasutati kõige enam vaakumaspiratsiooni (90,8%); umbes 7/8 abortidest (92,6 %) tehti narkoosis. Enamike abortide korral (99,2%) tüsistusi ei esinenud.

## SUMMARY

### **Births, fertility**

From 1992 to 1998, both the annual number of births in Estonia and the number of live births per 1000 women of childbearing age decreased. In 1992, the annual number of births was 18 191 and the number of live births per 1000 women of childbearing age was 48.6. In 1998, these figures were 12 204 and 35.1, respectively. In 1999 and 2000 the fertility rate slightly increased, but in 2001 again decreased. In 2001 the annual number of births was 12 690 and the number of live births per 1000 women of childbearing age was 36.8. By county, the fertility rate per 1000 women of childbearing age was the highest in Valgamaa, followed by Lääne-Virumaa and Jõgevamaa; the lowest fertility rate was in Ida-Virumaa, followed by Harjumaa.

### *Perinatal mortality*

From 1992 to 2001, perinatal mortality in Estonia decreased. In 1992, the perinatal mortality rate per 1000 births was 20.1, in 2001, 8.0. This decrease in perinatal mortality was caused both by a decrease in the stillbirth rate and by a decrease in the early neonatal mortality rate, (the early neonatal mortality decreased more than the stillbirth rate).

Perinatal mortality decreased, both in the hospitals of III stage i.e. higher hospitals (1000 or more births per year), and in the hospitals of II stage (less than 1000 births per year), however, perinatal mortality remained a bit higher in the hospitals of III stage. This is understandable, as in the hospitals of III stage i.e. higher hospitals (Ida-Tallinn Central Hospital, Lääne-Tallinn Central Hospital and Tartu University Clinics), high-risk pregnant women are referred from hospitals of lower stages, which serve the districts.

### *Women*

During the period 1992–2001, the average maternal age increased from 25.5 years to 27.1 years. The average maternal age increased both for primiparas and for women who had one or more previous deliveries. With the increase of maternal age the average paternal age increased too. The proportion of employed women among mothers decreased and the proportions of unemployed women, housewives and students among mothers increased. The family status of mothers changed significantly. The proportion of married mothers decreased (from 66.3% in 1992 to 43.4% in 2001) and the proportions of cohabiting and single mothers increased. Among the various ethnic groups, the proportion of Estonian mothers increased from 70.4% in 1992 to 73.6% in 1993, but thereafter it gradually decreased and was 70.1% in 2001.

From 1992 to 2001, the proportion of women who started their antenatal visits before the 12<sup>th</sup> week of gestation increased. In 1992 these women made up 49.7% of all women who visited a gynaecologist or midwife, rising to 67.6% in 2001. At the same time, the number of antenatal visits increased. In 2001 the average number of antenatal visits was 10.3, and 9.7 of them were visits to gynaecologist.

Among examinations during pregnancy, the number of ultrasounds performed before the 21<sup>st</sup> week of gestation increased significantly. In 1992, the number of ultrasound examinations per 100 mothers was 30, in 2001, 86. Of the possible risk factors and complications during the same time period, the proportions of previous Caesarean sections, anaemia and threatened abortions increased, the proportions of hypertensive disease, pre-eclampsia, renal diseases and threatened preterm deliveries decreased.

During the period 1992–2001, there have been remarkable changes in the frequency of certain types of delivery, with the proportion of vaginal deliveries decreasing and the proportion of Caesarean sections increasing. In 1992 Caesarean sections accounted for 6.4% of births, whereas the percentage rose to 15.6% in 2001. From 1992 to 2001 the proportion of preterm deliveries declined somewhat, from 6.6% to 5.8%.

From 1992 to 2001, the proportions of electronic monitoring and pH measurement of the fetus, artificial rupture of membranes, induced delivery and asphyxia increased, however the proportion of perineotomy and episiotomy decreased.

The proportion of family deliveries steadily increased. In 1992 family deliveries made up 12.6% of all deliveries, and in 2001, 56.2%. The percentage of family deliveries was the highest in hospitals of III stage and the lowest in larger hospitals of II stage.

### *Infants*

The number of births is not distributed equally throughout the year. As an average of ten years (1992–2001), the proportion of born infants was the largest in early spring (in March), and the smallest in late autumn (in November). More boys (51.6%) were born than girls (48.4%).

In 1992–2001, the proportion of infants born in-hospital increased slightly and the proportion of infants born outside the hospital decreased. There were fewer stillbirths among hospital births than among births occurring outside the hospital or in transport to the hospital.

From 1992–2001, the average birthweight of newborns generally increased (54 g). In 2001, the average birthweight of newborns was 3489 g (3561 g for boys and 3413 g for girls). The proportion of births was the highest in the weight group 3500–3999 g, and the proportion of infant deaths in the early neonatal period was the highest in the weight group 500–999 g.

The proportions of respiratory distress and birth trauma among newborn diagnoses decreased. Often infants were discharged or referred for further treatment at another hospital by the end of their first week of life. In 1992, the proportion of newborns still in the maternity ward at the age of seven days was 8.4%; in 2001, 1.8%.

## **Abortions**

During the period of 1992–2001, both the annual number of abortions and the abortion rate steadily decreased. In 1992, the annual number of legally induced abortions (i.e. performed according to a woman's request or medical indications) was 25 803 and the number of abortions per 1000 women of childbearing age was 69.6. In 2001, these figures were 11 656 and 34.0, respectively. The number of legally induced abortions per 100 live births was lower in 2001 than in 1992 (92.4 and 143.3, respectively).

By county, the level of abortions (both, their number per 1000 women of childbearing age and their number per 100 live births) was the highest in Ida-Virumaa and the lowest in islands (Saaremaa and Hiiumaa) in 2001.

In 2001, the average age of women who had abortions was 28.2 years; nearly a fourth of them (25.3%) had no previous delivery. More than half of the women who had an abortion (57.9%) had not used any contraceptives immediately before becoming pregnant. The proportion of women who had not used contraceptives was higher among very young women (under 20 years) and women at the end of childbearing age. The proportion of Estonian women who have had an abortion was 57.5%, less than the proportion of women who have had a delivery (70.1%). Single women were more likely to end a pregnancy by abortion.

Legally induced abortions made up the majority (82.9%) of all abortions in Estonian health care institutions in 2001, the mean gestational age for a legal abortion was 7.7 weeks. The most common method of abortion was vacuum aspiration (used in 90.8% of cases). About 7/8 of abortions (92.6%) were performed under intravenous medication. There were no complications in the majority of abortions (99.2%).

# METOODIKA

## Definitsioonid

Alates 1992. aastast kasutatakse Eestis elusalt ja surnult sündinud lapse määratlemiseks rahvusvahelisi kriteeriume. Vastsündinu, kes on sündinud kehamassiga vähemalt 500 g alates 22. rasedusnädalast ja kellel on vähemalt üks elutunnustest (iseseisev hingamine, südamelöögid, nabaväadi pulsatsioon või tahte alluvate lihaste ilmsed liigutused), on *elusalt sündinud laps*. *Surnult sündinuks* loetakse vastsündinu kehamassiga vähemalt 500 g alates 22. rasedusnädalast eelnimetatud elutunnusteta.

*Antenataalne surm* on loote surm enne sünnituse algust.

*Intranataalne surm* on loote surm sünnituse ajal.

*Perinataalne surm* on surm perinataalperioodis (alates 22 täis-rasedusnädala möödumisest kuni 7 päeva täissaamiseni pärast sündi).

*Varane neonataalne surm* on surm varases neonataalperioodis (alates sünnist kuni 7 päeva täissaamiseni pärast sündi).

*Spontaanabort* on raseduse iseeneslik katkemine (RHK-10 kood O03).

*Legaalselt indutseeritud abort* on raseduse katkestamine naise omal soovil või meditsiinilistel näidustustel (RHK-10 kood O04).

*Legaalne abort* on raseduse katkestamine naise omal soovil enne 12. rasedusnädalat (RHK-10 kood O04).

*Terapeutiline abort* on raseduse katkestamine meditsiinilistel näidustustel (RHK-10 kood O04).

## Arvutused

Sünniandmete aastatöötuse aluseks on lapse sünnikuupäev, abordiandmete korral abordi kuupäev.

Kordajate arvutamisel on kasutatud Eesti Statistikaameti poolt avaldatud aastakeskmist rahvaarvu ja rahvastiku koosseisu. Üheksakümnendate aastate rahvastikuandmed on korrigeeritud 1989. ja 2000. aasta rahvaloenduste andmete alusel.

*Sündimuse üldkordaja* leidmiseks on aasta jooksul elusalt sündinud laste arv jagatud aastakeskmise elanike arvuga ja korrutatud 1000ga.

*Sündimuse erikordaja* leidmiseks on aasta jooksul elusalt sündinud laste arv jagatud fertiilses eas (15–49 aastat) naiste aastakeskmise arvuga ja korrutatud 1000ga.

*Summaarne sündimuskordaja* on aasta vanuskordajate summa (5-aastaste vanuserühmade puhul korrutatuna viiega).

*Surnultsündimuskordaja* leidmiseks on aasta jooksul surnult sündinud laste arv jagatud kõikide sündide arvuga ja korrutatud 1000ga.

*Perinataalsuremuskordaja* leidmiseks on aasta jooksul perinataalperioodis surnud laste arv jagatud kõikide sündide arvuga ja korrutatud 1000ga.

*Varase neonataalsuremuskordaja* leidmiseks on aasta jooksul varases neonataalperioodis surnud laste arv jagatud elussündide arvuga ja korrutatud 1000ga.

*Abortiivsuskordaja* leidmiseks on aasta jooksul toimunud abortide arv jagatud fertiilses eas (15–49 aastat) naiste aastakeskmise arvuga ja korrutatud 1000ga.

*Summaarne abortiivsuskordaja* on aasta vanuskordajate summa (5-aastaste vanuserühmade puhul korrutatuna viiega).

*Abordimäära* leidmiseks on aasta jooksul toimunud abortide arv jagatud elussündide arvuga ja korrutatud 100ga.

*Keskmiised* on kõikidel juhtudel arvutatud kui aritmeetilised keskmised. Keskmise vanuse arvutamisel on iga indiviidi vanus aastates võetud arvesse sajandikulise täpsusega.

## METHODOLOGY

### Definitions

Since 1992, the international criteria of live and stillbirth of children has been used in Estonia. A *live born child* is a newborn with a birthweight of at least 500 g, carried to the 22<sup>nd</sup> week of pregnancy, and with at least one characteristic of life (independent breathing, beating of the heart, pulsation of the umbilical cord, or definite movement of voluntary muscles). A newborn with a birthweight of at least 500 g, carried to the 22<sup>nd</sup> week of pregnancy and without the aforementioned characteristics of life is considered *stillborn*.

*Antenatal death* is the death of a fetus before delivery.

*Intranatal death* is the death of a fetus during delivery.

*Perinatal death* is the death of a fetus in the perinatal period (from 22 full-weeks of pregnancy until 7 days after birth).

*Early neonatal death* is the death of an infant in the early neonatal period (from birth until 7 days after birth).

*Spontaneous abortion* is the spontaneous termination of a pregnancy (ICD-10 code O03).

*Legally induced abortion* is the termination of a pregnancy according to a woman's request or medical indications (ICD-10 code O04).

*Legal abortion* is the termination of a pregnancy according to a woman's request, before the 12<sup>th</sup> week of gestation (ICD-10 code O04).

*Therapeutic abortion* is the termination of a pregnancy due to medical indications (ICD-10 code O04).

### Calculations

The basis for yearly processing of the birth data is the date of birth of the child; of the abortion data, the date of the abortion.

To calculate rates, the mean annual number and the composition of the population, published by the Statistical Office of Estonia, has been used. The population data of the nineties are corrected on the basis of the data of 1989 and 2000 population census.

To calculate *the crude birth rate*, the number of children born alive during the year was divided by the mean annual number of population and multiplied by 1000.

To calculate *the fertility rate*, the number of children born alive during the year was divided by the mean annual number of women of childbearing age (15–49 years) and multiplied by 1000.

*Total fertility rate* is the sum of the fertility rates by age of mothers (multiplied by five in the case of 5-year age groups).

To calculate *the stillbirth rate*, the number of children born dead during the year was divided by the annual number of all births and multiplied by 1000.

To calculate *the perinatal mortality rate*, the number of children who died in the perinatal period during the year was divided by the annual number of all births and multiplied by 1000.

To calculate *the early neonatal mortality rate*, the number of children who died in the early neonatal period during the year was divided by the annual number of live births and multiplied by 1000.

To calculate *the abortion rate*, the number of abortions occurred during the year was divided by the mean annual number of women of childbearing age (15–49 years) and multiplied by 1000.

*Life-time abortion rate* is the sum of the abortion rates by age of women (multiplied by five in the case of 5-year age groups).

To calculate *the abortion ratio*, the number of abortions occurred during the year was divided by the mean annual number of live births and multiplied by 100.

*Means* are calculated in all cases as arithmetic means. To calculate mean age, each person's centesimal age was used. For example, age 20 years 6 months would be represented as 20.5 years.
